Social evidence-based resource-constrained cognitive-behavioral model

Unquestioned truths and beliefs

Beer is a drink
Coffee is a drink
Tea is a drink
Juice is a drink

Social connections, with account to levels of trust

Mary is my best friend
Peter is my friend
Bob is Peter's friend

Facts weighed based on their social sources and assessments, in the light of unquestioned beliefs

★★★ I like juice very much
★★ I like tea
★ I may try coffee
I won't try beer

Facts obtained from sources with different levels of trust

Bob said beer is good
Mary said beer is not good
Mary said juice is good
Mary said tea is good
Peter said juice is good
Peter said coffee is good

Perception & Action driven by Believed Social Evidence

i – person of consideration
j – concept (action) of consideration (exposed evidence)
l – person's belief item (of foundation graph of size L - personal preference base)
k – person's correspondent (of social graph of size K - social reference base)
B_{il} – person's i mental attachment to l (personal preference)
S_{ik} – person's i social bind to k (social reference)

recursion

R^B R^S

$$P_{ij} = \Sigma_{l=1,L}(E^B_{ijl} * B_{il}) * \Sigma_{k=1,K}(E^S_{ijk} * S_{ik})$$ *(what we think)*

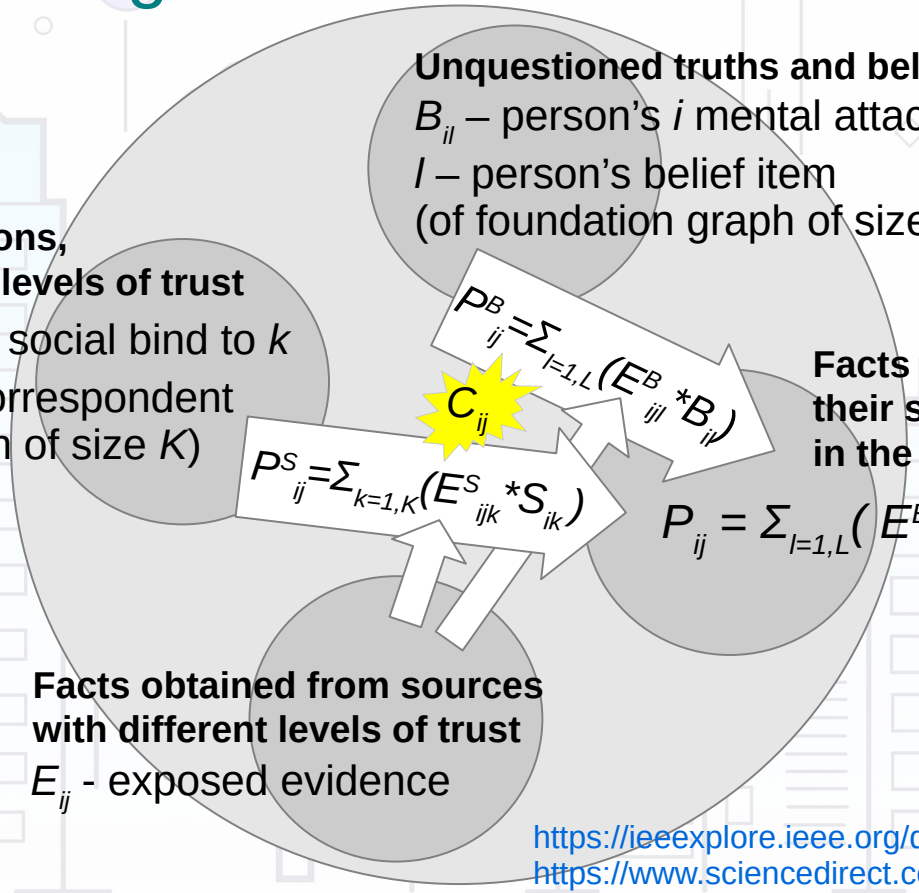

E^B_{ik} – concept (action) j agreement or compatibility with l in mind of i (believed evidence)
E^S_{ik} – concept (action) j expression or confirmation by k in view of i (social evidence)
P_{ij} – concept (action) j power for i (personal evidence)

$$C_{ij} = L + K + R^B + R^S$$ *(why we don't think about that)*

C_{ij} – concept (action) cost j cost for i (personal cost)

Consensus – technology to govern distributed multi-agent systems such as blockchains or societies, resistant to takeover and scam.

Proof-Of-Work

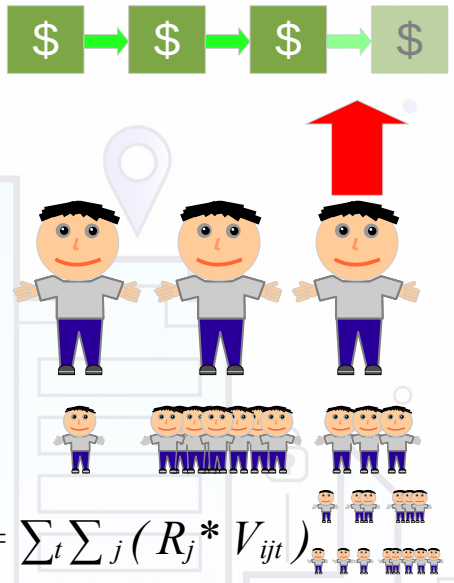

Force is Power:
Those who own more computing resources govern the network.

Proof-Of-Stake

Money is Power:
Those who have more money govern the network.

Proof-Of-Reputation

$$R_i = \sum_t \sum_j (R_j * V_{ijt})$$

Reputation is Power:
Those who earn a better reputation and a greater long-term audience base govern the network.

Weighted Liquid Rank

https://arxiv.org/pdf/1806.07342

Algorithm 1 Weighted Liquid Rank (simplified version)

Inputs:
1) Volume of rated transactions each with financial value of the purchased product or service and rating value evaluating quality of the product/service, covering specified period of time;
2) Reputation ranks for every participant at the end of the previous time period.

Parameters: List of parmeters, affecting computations - default value, logarithmic ratings, conservatism, decayed value, etc.

Outputs: Reputation ranks for every participant at the end of the previous time period.

1: **foreach of** *transactions* **do**
2: **let** *rater_value* be rank of the rater at the end of previous period of default value
3: **let** *rating_value* be rating supplied by trasaction rater (consumer) to ratee (supplier)
4: **let** *rating_weight* be financial value of the transaction of its logarithm, if logarithmic ratings parameter is set to true
5: **sum** *rater_value*rating_value*rating_weight* for every ratee
6: **end foreach**
7: **do** normalization of the sum of the muliplications per ratee to range *0.0-1.0*, get *differential_ranks*
8: **do** blending of the old_ranks known at the end of previous peiod with differential_ranks based on parameter of conservatism, so that *new_ranks* = *(old_ranks*conservatism+N*(1-differential_ranks))*, using decayed value if no rating are given to ratee during the period
9: **do** normalization of *new_ranks* to range *0.0-1.0*
10: **return** *new_ranks*

- R_d - default initial reputation rank;
- R_c - decayed reputation in range to be approached by inactive agents eventually;
- *C* - conservatism as a blending "alpha" factor between the previous reputation rank recorded at the beginning of the observed period and the differential one obtained during the observation period;
- *FullNorm* – when this boolean option is set to *True* the reputation system performs a full-scale normalization of incremental ratings;
- *LogRatings* - when this boolean option is set to *True* the reputation system applies *log10(1+value)* to financial values used for weighting explicit ratings;
- *Aggregation* - when this boolean option is set to *True* the reputation system aggregates all explicit ratings between each unique combination of two agents with computes a weighted average of ratings across the observation period;
- *Downrating* - when this boolean option is set to *True* the reputation system translates original explicit rating values in range *0.0-0.25* to negative values in range *-1.0* to *0.0* and original values in range *0.25-1.0* to the interval *0.0-1.0*.
- *UpdatePeriod* – the number of days to update reputation state, considered as observation period for computing incremental reputations.

What can be learned about the psyche of a society from its texts?

Cognitive Distortions (Cognitive-Behavioral Therapy)

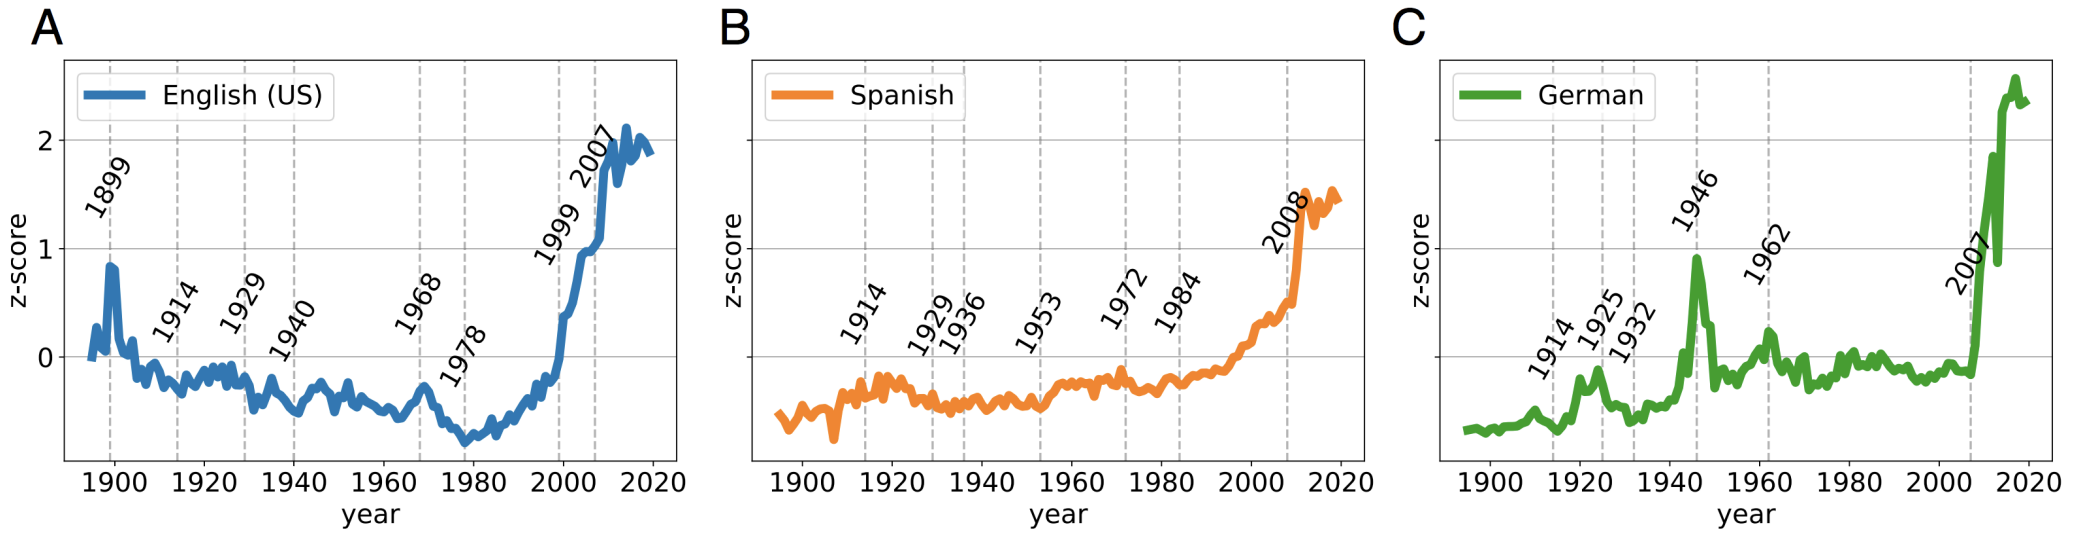

Fig. 2. (*A*–*C*) Median z scores of time series of CDS n-gram prevalence from 1855 to 2020 (125 y) in US English (*A*), Spanish (*B*), and German (*C*) with year markers added for major historical events. All time series reveal stable or declining levels for most of the 20th century followed by a sharp surge of cognitive distortions in the past three decades. US English shows declining levels from 1899 to 1978, with minor peaks around 1914 and 1940 (World War I and World War II) and notably 1968. This decline is followed by a surge of CDS prevalence starting in 1978 that continues to 2019. For Spanish we find stable levels from 1895 to the early 1980s at which point a trend occurs toward higher CDS prevalence levels above any of those previously observed. German shows stable CDS prevalence levels, with the exception of strong peaks around and after World War I and World War II, until 2007 at which point a sudden surge occurs.

Automated detection of cognitive distortions, emotions and social situations

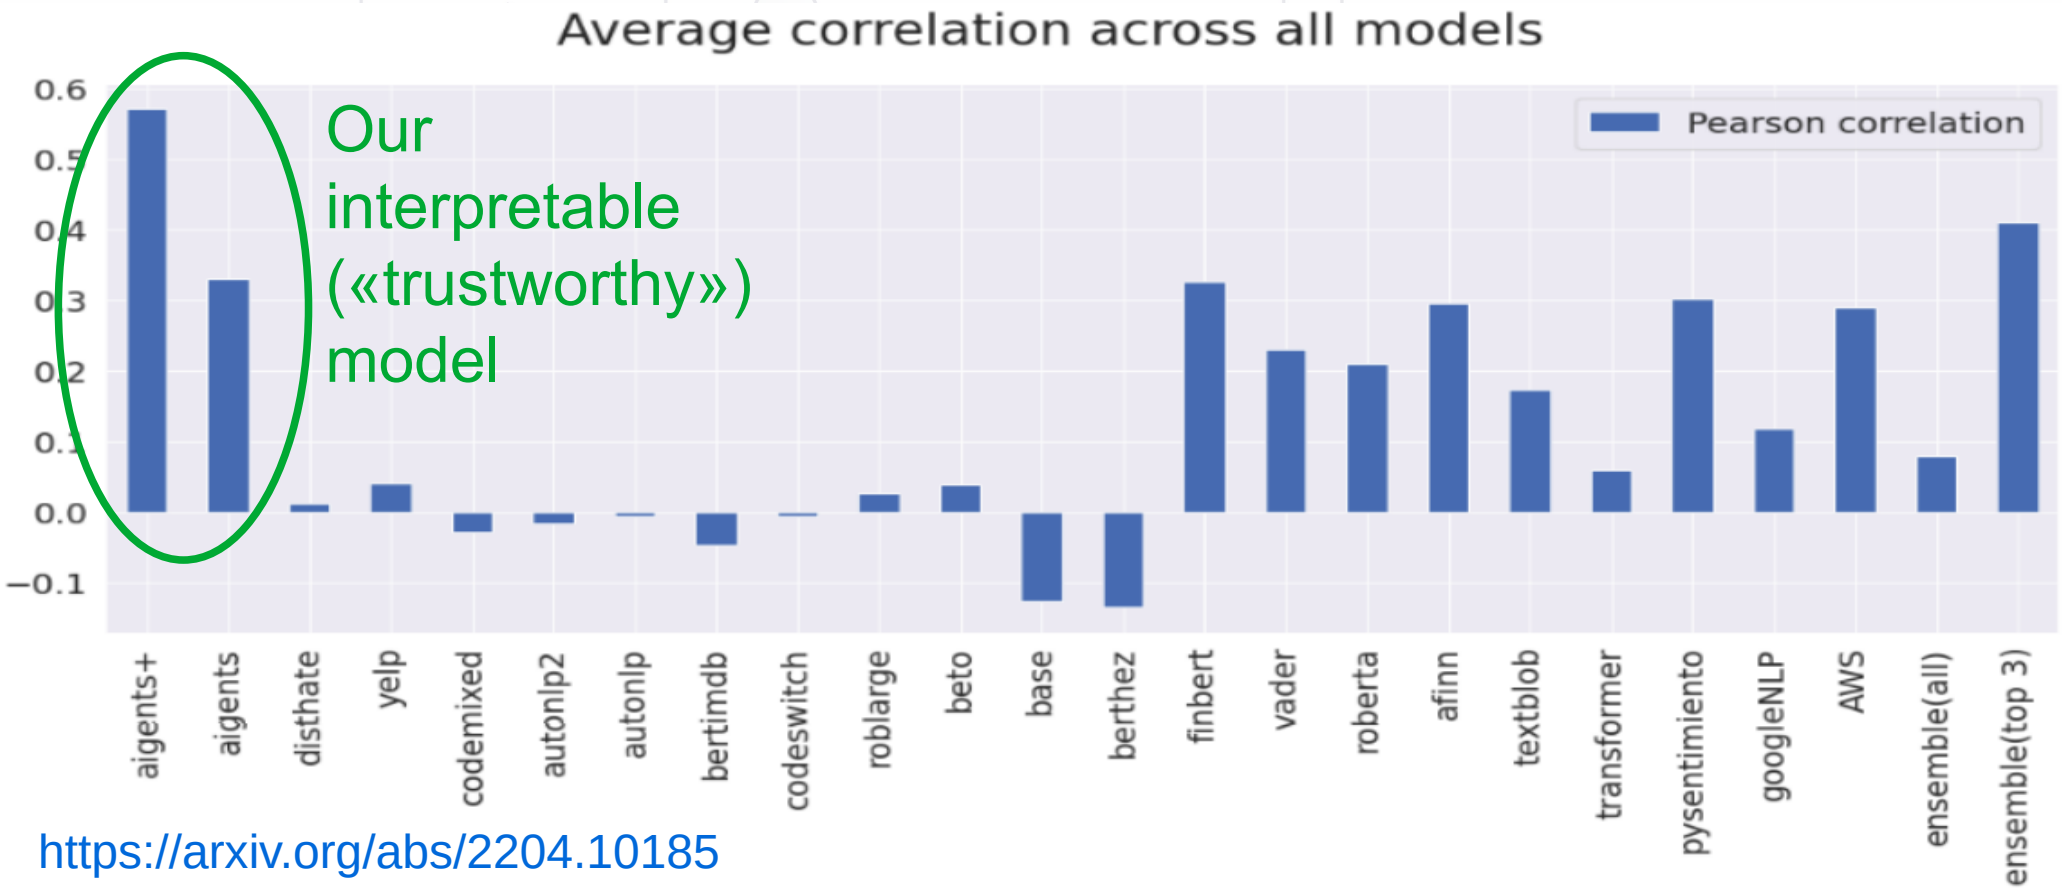

P: Hi! How are you?
K: Bad. They have kicked out the loser! (tentatively diagnosing #being fired and #personalization)
P: How did that happen? Who did that? (clarifying **social situation**)
K: It was my job. I am fired so to speak. (confirming #being fired)
P: Does it make you anxious or make you angry on them? (clarifying **emotion** - #anxiety or #anger)
K: Anxious, of course. I have to pay the mortgage. (confirming #anxiety, diagnosing #shouldment)
P: You have been fired from your job and you are afraid, that won't be able to pay, right? (#being fired, #anxiety)
K: Yes. (confirming diagnosis in respect to **social situation** and **emotion**)
P: What do you think was the reason?
K: I just was not lucky – the investor has left the company. (diagnosing #personalization)
P: Was that your fault? (clarifying **cognitive distortion** - #personalization)
K: Not at all. I just feel like my life is ruined. (change diagnosis to #catastrophizing)
P: You are anxious, that after the being fired you won't be able to find a new job, correct? (#anxiety, #being fired, #catastrophizing)
K: Exactly. Although in fact I am an experienced professional. (confirming diagnosis in regard to **emotion**, **social situation** and **cognitive distortion** moving on to correction with healing interventions)

Robert Cialdini: Social Proof

Social proof is a psychological and social phenomenon wherein people copy the actions of others in choosing how to behave in a given situation. The term was coined by Robert Cialdini in his 1984 book Influence: Science and Practice, and the concept is also known as informational social influence.
